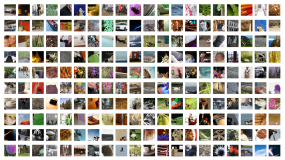
Virtual Talk at ICML 2021
July 18-24, 2021

The Big Data Deluge and AI

- Many popular AI tasks, e.g., tasks in computer vision, natural language processing, speech processing, are in dire demand for

large amount of high quality labeled data



Millions of labeled images in ImageNet dataset (www.image-net.org)

Data Labeling

- **Labeling is not a trivial task!**
  - need to label large volume of data
  - need some level of expertise to produce high quality labels

Millions of contract workers annotate machine learning data

Data Labeling: AI's Human Bottleneck

Crowdsourcing - Using Power of the Crowd

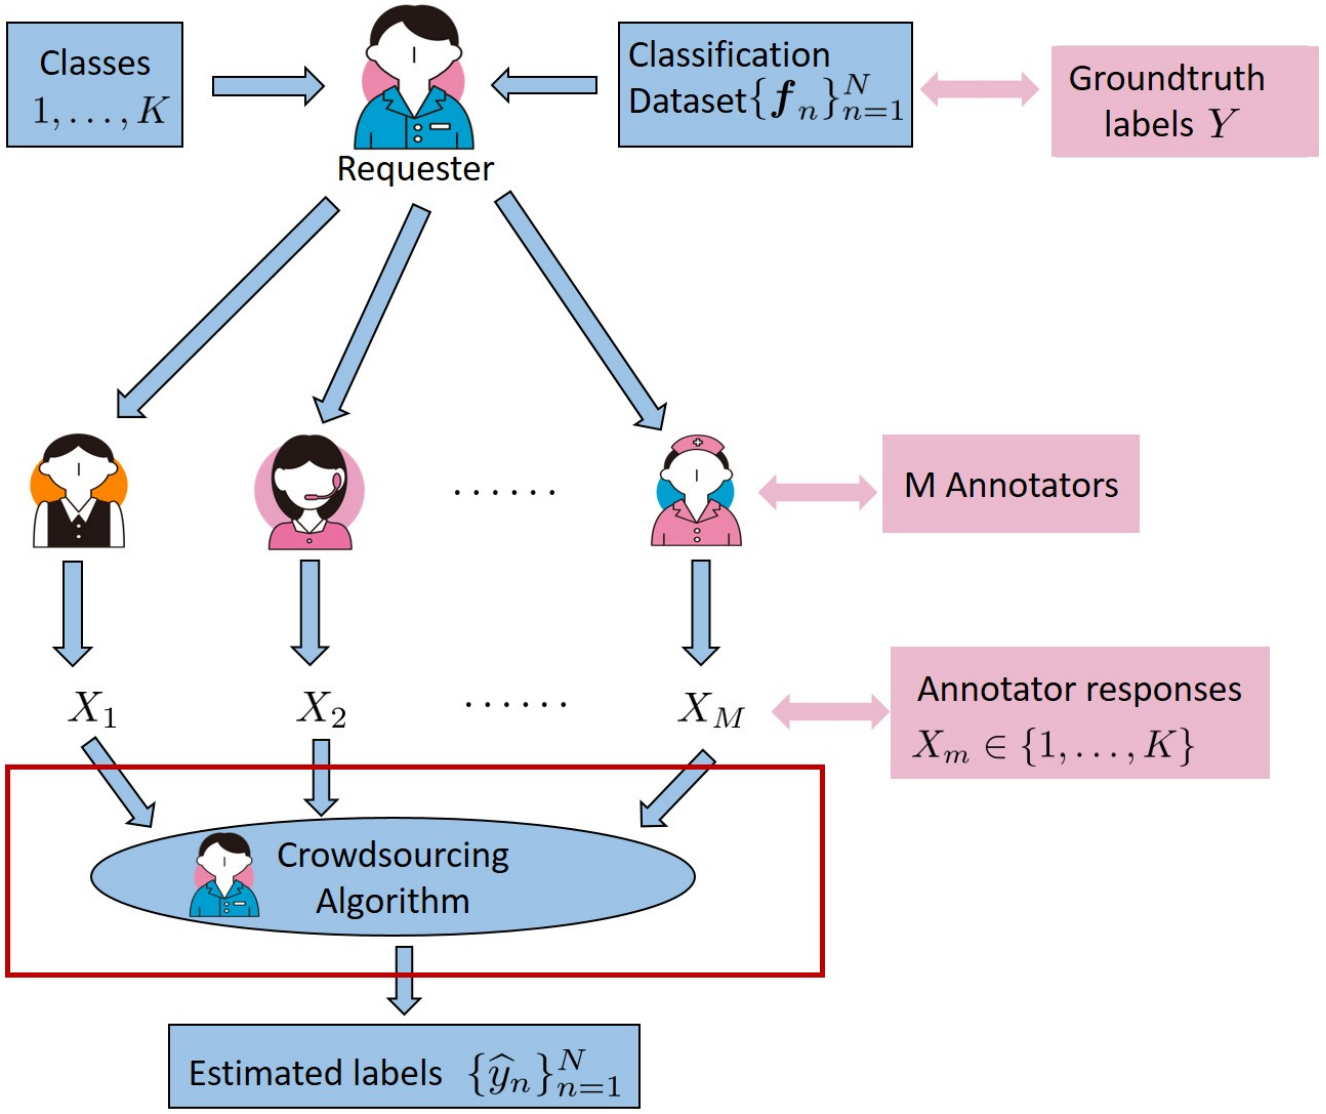
- **Crowdsourcing** techniques
  - ☐ employ a group of annotators to label the data items
  - ☐ integrate the acquired labels

Source: https://ideascale.com/innovation

- Crowdsourcing platforms have self-registered annotators who
  - ☐ may not be well-trained
  - ☐ not all annotators label all the data

Hence, simple integration strategies like majority voting may work poorly

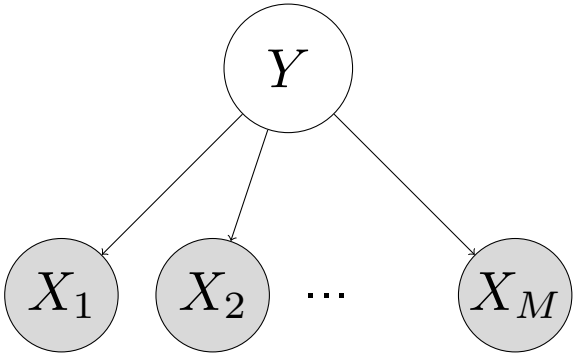
Crowdsourcing Dataflow



Dawid-Skene Model

- Annotation integration is a long-existing research topic in machine learning
- Dawid and Skene [1979] formulated this as **model identification problem**

Source: https://www.trakken.de/insight



- a naive Bayes model
- simple and effective
- based on conditional independence of annotations

Dawid-Skene Model

- Under naive Bayes,

$$\Pr(X_1 = k_1, \ldots, X_M = k_M) = \sum_{k=1}^{K} \Pr(Y = k) \prod_{m=1}^{M} \Pr(X_m = k_m | Y = k)$$

- Define the **confusion matrix** $\boldsymbol{A}_m \in \mathbb{R}^{K \times K}$ for each annotator and the **prior probability vector** $\boldsymbol{\lambda} \in \mathbb{R}^K$ such that

$$\boldsymbol{A}_m(k_m, k) := \Pr(X_m = k_m | Y = k) \qquad \boldsymbol{\lambda}(k) := \Pr(Y = k)$$

- One can build a maximum $a\ posteriori$ probability (MAP) estimator for y_n after identifying $\boldsymbol{A}_m$'s and $\boldsymbol{\lambda}$

Model Identification $\Longrightarrow$ Identify $\boldsymbol{A}_m$'s and $\boldsymbol{\lambda}$ $\Longrightarrow$ Label Integration

Prior Approaches with Dawid-Skene Model

- Dawid-Skene (D&S) Model & EM Algorithm [Dawid and Skene, 1979] :
  - No model identifiability & algorithm tractability
- Spectral Methods [Ghosh et al., 2011; Karger et al., 2011b]:
  - Identifiability established for simpler cases, for e.g., binary classification
- Bayesian Methods [Whitehill et al., 2009; Zhou et al., 2012]:
  - Extended D&S model considering "item difficulty" and "annotator ability"
  - No model identifiability
- Tensor Methods [Zhang et al., 2016; Traganitis et al., 2018]:
  - Using third-order co-occurrences of annotator responses, for e.g., $\Pr(X_m = k_m, X_\ell = k_\ell, X_j = k_j)$
  - Established model identifiability
  - High sample complexity due to third-order statistics
  - High computational cost from the tensor decomposition

Recent Development - Coupled NMF

- **Pairwise co-occurrence** of annotator responses: $\boxed{\boldsymbol{R}_{m,j} = \boldsymbol{A}_m \boldsymbol{D} \boldsymbol{A}_j^\top, \boldsymbol{D} = \mathrm{diag}(\boldsymbol{\lambda})}$

$$\underbrace{\mathsf{Pr}(X_m = k_m, X_j = k_j)}_{\boldsymbol{R}_{m,j}(k_m,k_j)} = \sum_{k=1}^{K} \underbrace{\mathsf{Pr}(Y=k)}_{\boldsymbol{\lambda}(k)} \underbrace{\mathsf{Pr}(X_m = k_m | Y = k)}_{\boldsymbol{A}_m(k_m,k)} \underbrace{\mathsf{Pr}(X_j = k_j | Y = k)}_{\boldsymbol{A}_j(k_j,k)}$$

  - less sample complexity compared to third-order statistics [Han et al., 2015]

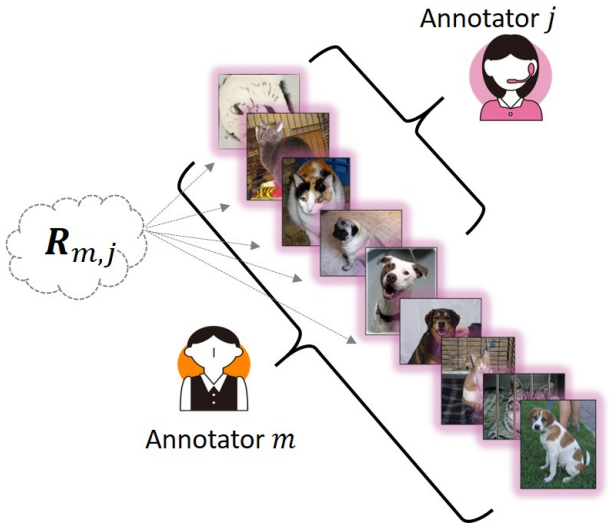
- If annotators m and j **co-label** some items, $\boldsymbol{R}_{m,j}$ can be estimated via sample averaging

- The CNMF criterion in [Ibrahim et al., 2019]:

$$\text{find } \{\boldsymbol{A}_m\}_{m=1}^M, \boldsymbol{\lambda}$$

$$\text{s.t. } \boldsymbol{R}_{m,j} = \boldsymbol{A}_m \boldsymbol{D} \boldsymbol{A}_j^\top, \ (m,j) \in \boldsymbol{\Omega}, \leftarrow \textit{observed set}$$

$$\boldsymbol{A}_m \geq \boldsymbol{0}, \boldsymbol{1}^\top \boldsymbol{A}_m = \boldsymbol{1}^\top, \ \boldsymbol{1}^\top \boldsymbol{\lambda} = 1, \boldsymbol{\lambda} \geq \boldsymbol{0}.$$



Dog images source : www.datasciencecentral.com

Identifiability Claim in CNMF

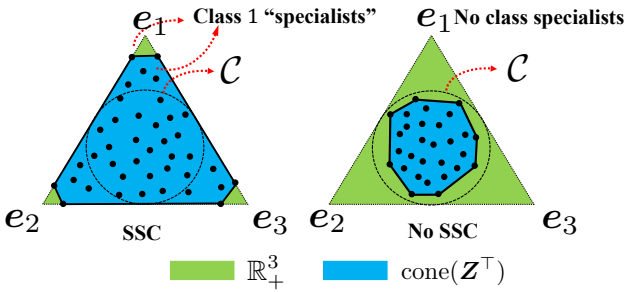
- Identifiability under the assumption that there exist two subsets of the annotators $\mathcal{P}_1$ and $\mathcal{P}_2$, where $\mathcal{P}_1 \cap \mathcal{P}_2 = \emptyset$ and $\mathcal{P}_1 \cup \mathcal{P}_2 \subseteq [M]$,

$$\boldsymbol{H}^{(1)} := [\boldsymbol{A}_{m_1}^\top, \ldots, \boldsymbol{A}_{m_{|\mathcal{P}_1|}}^\top]^\top, \quad \boldsymbol{H}^{(2)} := [\boldsymbol{A}_{j_1}^\top, \ldots, \boldsymbol{A}_{j_{|\mathcal{P}_2|}}^\top]^\top,$$

such that $\boldsymbol{H}^{(1)}$ and $\boldsymbol{H}^{(2)}$ satisfy the *sufficiently scattered condition* (SSC)

Definition 1: (SSC) [Fu et al., 2015]

Any nonnegative matrix $\boldsymbol{Z} \in \mathbb{R}_+^{I \times K}$ satisfies the SSC if the conic hull of $\boldsymbol{Z}^\top$ (i.e., cone$(\boldsymbol{Z}^\top)$) satisfies $\mathcal{C} \subseteq \text{cone}\{\boldsymbol{Z}^\top\}$ where $\mathcal{C} = \{\mathbf{x} \in \mathbb{R}^K \mid \mathbf{x}^\top \mathbf{1} \geq \sqrt{K-1}\|\mathbf{x}\|_2\}$.



- A row of $\boldsymbol{H}^{(i)}$ (i.e., a row of certain $\boldsymbol{A}_m$) close to kth unit vector implies that

$$\boldsymbol{A}_m(k,k) \approx 1 \quad \text{and} \quad \boldsymbol{A}_m(k,k_m) \approx 0, k_m \neq k \ \textbf{(class specialists)},$$

i.e., annotator m rarely confuses data from other classes with those from class k

Challenges in CNMF Framework

- **Identifiability Challenge:**
  - Both $\boldsymbol{H}^{(1)}$ and $\boldsymbol{H}^{(2)}$ satisfy the SSC $\Longrightarrow$ the disjoint $\mathcal{P}_1$ and $\mathcal{P}_2$ both contain "**class specialists**" for all K classes
  - The condition is somewhat restrictive

- **Computational Challenges:**
  - Recall the CNMF criterion in [Ibrahim et al., 2019]:

$$\begin{aligned} &\text{find } \{\boldsymbol{A}_m\}_{m=1}^{M}, \boldsymbol{\lambda} \\ &\text{s.t. } \boldsymbol{R}_{m,j} = \boldsymbol{A}_m \boldsymbol{D} \boldsymbol{A}_j^{\top}, \ (m,j) \in \boldsymbol{\Omega}, \leftarrow \ \textit{observed set} \\ &\boldsymbol{A}_m \geq \boldsymbol{0}, \boldsymbol{1}^{\top}\boldsymbol{A}_m = \boldsymbol{1}^{\top}, \ \boldsymbol{1}^{\top}\boldsymbol{\lambda} = 1, \boldsymbol{\lambda} \geq \boldsymbol{0} \end{aligned}$$

    $*$ handled using KL-divergence based model fitting problem with constraints
  - The algorithm is hardly scalable
  - Unclear convergence guarantee even if there is no noise
  - Unclear identifiability guarantee when there is noise

Proposed Approach - SymNMF Framework

- Assume that all $\boldsymbol{R}_{m,j} = \boldsymbol{A}_m \boldsymbol{D} \boldsymbol{A}_j^\top$ are available for all $m, j \in [M]$

Symmetric Non-negative Matrix Factorization (SymNMF) Model

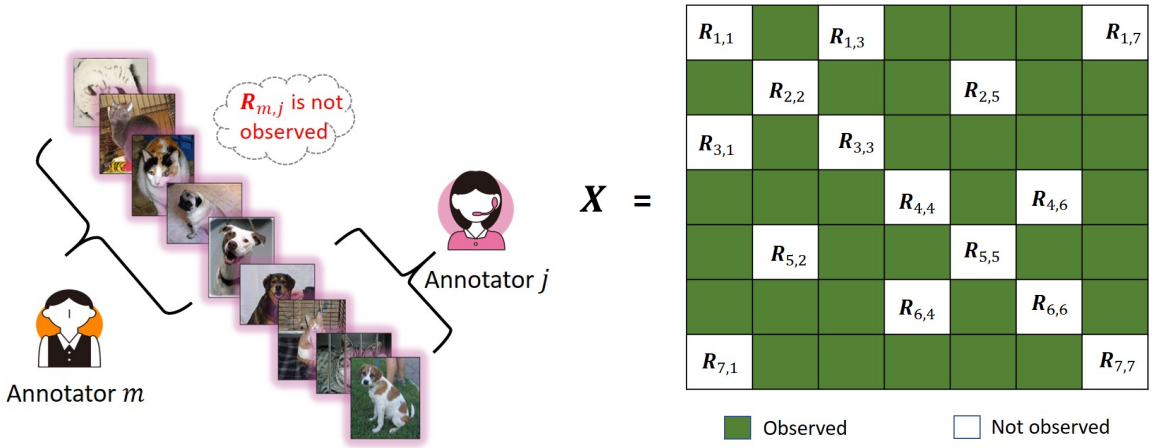
$$\boldsymbol{X} = \begin{bmatrix} \boldsymbol{R}_{1,1} & \dots & \boldsymbol{R}_{1,M} \\ \vdots & \ddots & \vdots \\ \boldsymbol{R}_{M,1} & \dots & \boldsymbol{R}_{M,M} \end{bmatrix} = \underbrace{[\boldsymbol{A}_1^\top, \dots . \boldsymbol{A}_M^\top]^\top \boldsymbol{D}^{1/2}}_{\boldsymbol{H}} \underbrace{\boldsymbol{D}^{1/2} [\boldsymbol{A}_1^\top, \dots . \boldsymbol{A}_M^\top]}_{\boldsymbol{H}^\top}$$

- **If $\boldsymbol{H}$ satisfies SSC**, the SymNMF model is unique [Huang et al., 2014], i.e., **$\boldsymbol{A}_m$'s and $\boldsymbol{\lambda}$ can be identified upto common column permutations**

- SSC of $\boldsymbol{H}$ $\implies$ only one set of "**class specialists**" is needed
  - recall that the CNMF framework in [Ibrahim et al., 2019] needs two disjoint sets of annotators $\mathcal{P}_1$ and $\mathcal{P}_2$ both contain "**class specialists**" for all K classes
  - much easier to satisfy compared to the CNMF framework case

Missing Co-occurrences

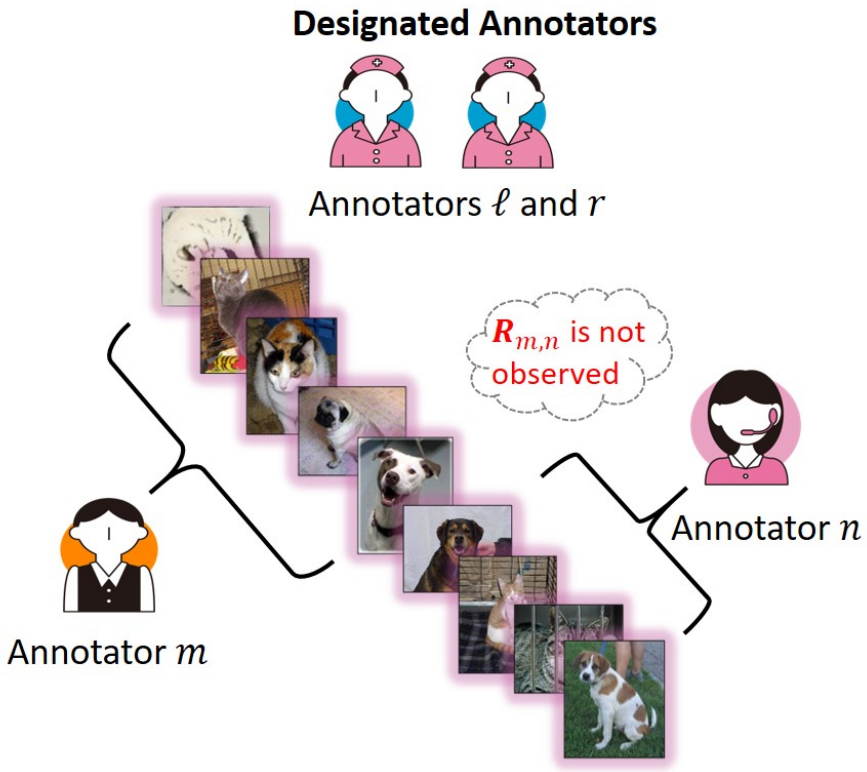
- The challenge in SymNMF framework is that many $\boldsymbol{R}_{m,j}$'s may be missing:
  - $\boldsymbol{R}_{m,m} = \boldsymbol{A}_m \boldsymbol{D} \boldsymbol{A}_m^\top$, $\forall m$ **do not have physical meaning** and thus cannot be observed
  - if annotators m, j **never co-labeled any items**, $\boldsymbol{R}_{m,j}$ is missing



- Imputing unobserved blocks ($\boldsymbol{R}_{m,j}$'s) can help estimate $\boldsymbol{H}$ from the SymNMF
- **How to impute $\boldsymbol{R}_{m,j}$'s with provable guarantees?**

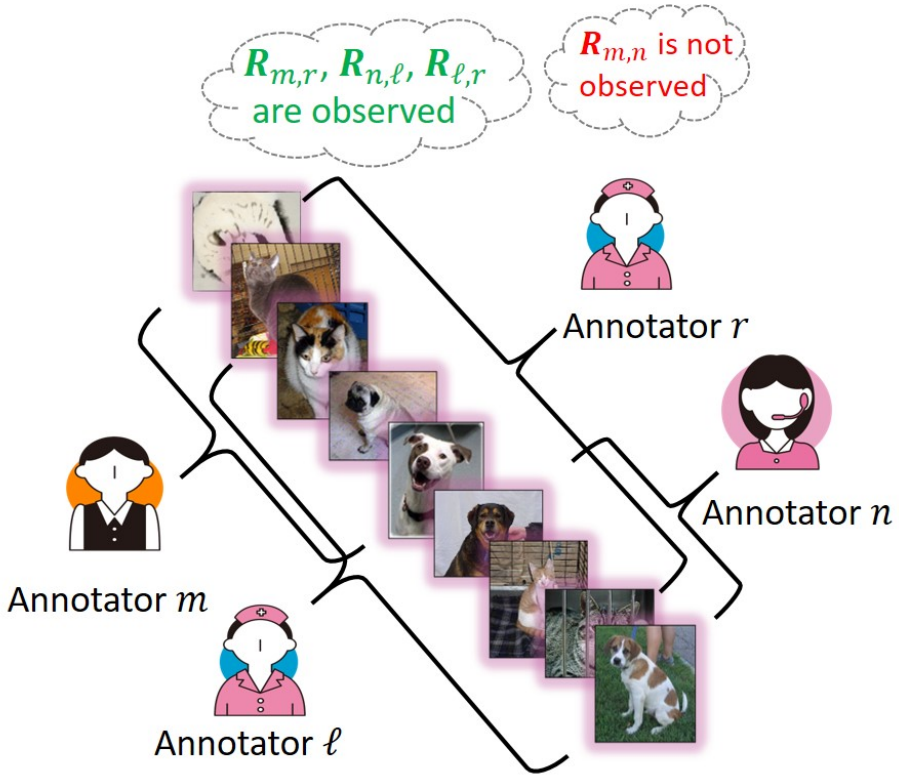
Designated Annotators-based Imputation

- In crowdsourcing, some annotators may be $designated$ to co-label items with other annotators.

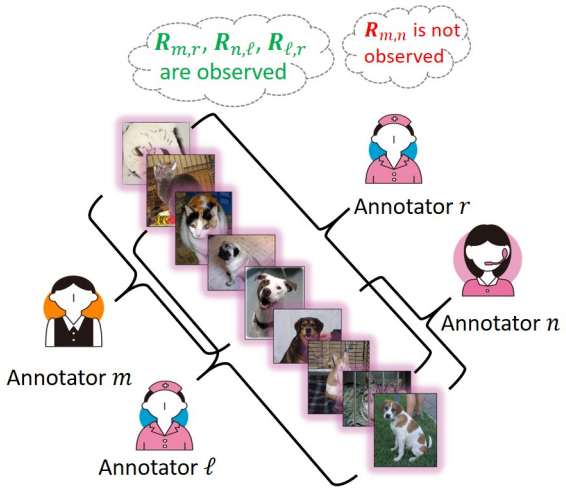


Designated Annotators-based Imputation

- In crowdsourcing, some annotators may be $designated$ to co-label items with other annotators.



Designated Annotators-based Imputation



1. $\boldsymbol{C} \longleftarrow [\boldsymbol{R}_{m,r}^\top, \boldsymbol{R}_{\ell,r}^\top]^\top$
2. $\boldsymbol{C} \overset{\text{thin SVD}}{\longrightarrow} [\boldsymbol{U}_m^\top, \boldsymbol{U}_\ell^\top]^\top \boldsymbol{\Sigma}_{m,\ell,r} \boldsymbol{V}_r^\top$
3. $\boldsymbol{R}_{m,n} \longleftarrow \boldsymbol{U}_m \boldsymbol{U}_\ell^{-1} \boldsymbol{R}_{n,\ell}^\top$

The diagonal blocks $\boldsymbol{R}_{m,m}$'s can be estimated by asking annotators ℓ, r to estimate $\boldsymbol{R}_{m,\ell}$, $\boldsymbol{R}_{m,r}$, and $\boldsymbol{R}_{\ell,r}$

Theorem 1: (Informal)

Assume that $\boldsymbol{R}_{m,r}$, $\boldsymbol{R}_{n,\ell}$ and $\boldsymbol{R}_{\ell,r}$ are estimated using at least S items and that $\kappa(\boldsymbol{A}_m) \leq \gamma$ and $\mathrm{rank}(\boldsymbol{A}_m) = \mathrm{rank}(\boldsymbol{D}) = K$ for all m. Suppose that S is above certain threshold. Then, any unobserved $\boldsymbol{R}_{m,n}$ can be estimated via (1)-(3), with probability of at least $1 - \delta$ such that $\|\widehat{\boldsymbol{R}}_{m,n} - \boldsymbol{R}_{m,n}\|_{\mathrm{F}} = O\left(K^2 \gamma^3 \sqrt{\log(1/\delta)/S}\right)$.

- **What if we do not have designated annotators?**

Robust Co-occurrence Imputation Criterion

$$\underset{\boldsymbol{U}_m, \boldsymbol{U}_j,\ \forall (m,j)\in \boldsymbol{\Omega}}{\text{minimize}} \sum_{(m,j)\in\boldsymbol{\Omega}} \|\widehat{\boldsymbol{R}}_{m,j} - \boldsymbol{U}_m \boldsymbol{U}_j^\top\|_{\mathrm{F}}$$

$$\text{subject to } \|\boldsymbol{U}_m\|_{\mathrm{F}} \le D_{(\textit{certain upper bound})},\ \forall m$$

- block ℓ_2/ℓ_1-mixed norm based criterion
- $\widehat{\boldsymbol{R}}_{m,j}$'s are estimated using unequal no of samples
- the formulation is robust under such unbalanced estimates

Theorem 2: Stability under Finite Samples

Assume that $\widehat{\boldsymbol{R}}_{m,j}$'s are estimated with $S_{m,j}$ samples, $\forall\ (m,j) \in \boldsymbol{\Omega}$ and each $\widehat{\boldsymbol{R}}_{m,j}$ is observed with the same probability. Let $\{\boldsymbol{U}_m^*, \boldsymbol{U}_j^*\}$ be any optimal solution of the above. Then we have

$$\frac{1}{L}\sum_{m<j} \|\boldsymbol{U}_m^*(\boldsymbol{U}_j^*)^\top - \boldsymbol{R}_{m,j}\|_{\mathrm{F}} \le C\sqrt{\frac{MK^2\log(M)}{|\boldsymbol{\Omega}|}} + \left(\frac{1}{|\boldsymbol{\Omega}|}+\frac{1}{L}\right)\sum_{(m,j)\in\boldsymbol{\Omega}} \frac{1+\sqrt{M}}{\sqrt{S_{m,j}}},$$

with probability of at least $1-3\exp(-M)$, where $L = M(M-1)/2$ and $C > 0$.

An iteratively reweighted algorithm (reminiscent of the ℓ_2/ℓ_1 mixed norm minimization [Chartrand and Yin, 2008]) is employed to solve the problem

Shifted ReLU Empowered SymNMF

Assuming that X is observed after co-occurrence imputation:

$$\boldsymbol{X} = \boldsymbol{H}\boldsymbol{H}^\top \xrightarrow{\text{square root decomposition}} \boldsymbol{X} \to \boldsymbol{U}\boldsymbol{U}^\top \implies \boldsymbol{U} = \boldsymbol{H}\boldsymbol{Q}^\top, \boldsymbol{Q} \text{ is orthogonal}$$

Estimation Criterion:

$$\underset{\boldsymbol{H},\boldsymbol{Q}}{\text{minimize}} \ \|\boldsymbol{H} - \boldsymbol{U}\boldsymbol{Q}\|_{\text{F}}^2$$

$$\text{subject to} \ \ \boldsymbol{H} \geq 0, \ \boldsymbol{Q}^\top\boldsymbol{Q} = \boldsymbol{I}$$

Proposed Algorithm:

$$\boldsymbol{H}_{(t+1)} \leftarrow \text{ReLU}_{\alpha_{(t)}}\left(\boldsymbol{U}\boldsymbol{Q}_{(t)}\right)$$ (**Orthogonal projection of each element of $\boldsymbol{U}\boldsymbol{Q}_{(t)}$ to $[\alpha_{(t)}, +\infty)$**)

$$\left.\begin{aligned} \boldsymbol{W}_{(t+1)}\boldsymbol{\Sigma}_{(t+1)}\boldsymbol{V}_{(t+1)}^\top &\leftarrow \text{svd}\left(\boldsymbol{H}_{(t+1)}^\top\boldsymbol{U}\right) \\ \boldsymbol{Q}_{(t+1)} &\leftarrow \boldsymbol{V}_{(t+1)}\boldsymbol{W}_{(t+1)}^\top \end{aligned}\right\}$$ (**Procrustes projection**)

- reminiscent of the SymNMF algorithm proposed in [Huang et al., 2014]
  - always uses $\alpha_{(t)} = 0$; convergence w/wo noise is unclear
- **elementwise shifted ReLU** operator is crucial for guaranteeing the convergence

Convergence of the Proposed SymNMF Algorithm

- Convergence analysis for SymNMF algorithms is challenging due to NP-hardness
  - global convergence/est. accuracy analysis is rarely seen
  - most existing SymNMF works showed only stationary point convergence [Huang et al., 2014; He et al., 2011]

Theorem 3: (Informal)

Consider $\widehat{\boldsymbol{U}} = \boldsymbol{H}\boldsymbol{Q}^\top + \boldsymbol{N}$. Denote $\nu = \|\boldsymbol{N}\|_{\mathrm{F}}$, $\sigma = \|\boldsymbol{H}\|_{\mathrm{F}}$, $h_{(t)} = \|\boldsymbol{H}_{(t)} - \boldsymbol{H}\boldsymbol{\Pi}\|_{\mathrm{F}}^2$ and $q_{(t)} = \|\boldsymbol{Q}_{(t)} - \boldsymbol{Q}\boldsymbol{\Pi}\|_{\mathrm{F}}^2$, where $\boldsymbol{\Pi}$ is any permutation matrix. Under the assumptions that,

- ☐ $\boldsymbol{H}$ is full rank and sparse enough; the energy of range space of $\boldsymbol{H}$ is well spread over its rows;
- ☐ the noise term ν and the initial error $q_{(0)}$ are small enough;

there exists $\alpha_{(t)} = \alpha > 0$, $\eta > 0$ and $0 < \rho < 1$ such that with high probability,

$$q_{(t)} \leq \rho q_{(t-1)} + O\left(K\sigma^2\nu^2\right), \quad h_{(t)} \leq 2\eta\sigma^2 q_{(t-1)} + 2\nu^2 \leftarrow \textbf{linear convergence}$$

- The rate parameter ρ is smaller (faster convergence) if $\boldsymbol{H}$ is sparser

Experiments - UCI Data

- 10 different MATLAB classifiers are trained and chosen as annotators
- Each annotator is allowed to label an item with prob. $p_m \in (0, 1]$; randomly choosing two annotators and letting them label with higher prob. (i.e., p_d)

Table 1: UCI Connect4 dataset ($N = 20,561$, $M = 10$, $K = 3$)

Algorithms	$p_m = 0.3$	$p_m \in (0.3, 0.5)$, $p_d = 0.8$	$p_m \in (0.5, 0.7)$, $p_d = 0.8$	**Time(s)**

Summary

- Proposed a **D&S model identification** based on:
  - **pairwise co-occurrences** of annotator responses
  - **SymNMF**-based framework that offers **strong identifiability**
- Two **lightweight algorithms for provably imputing missing co-occurrences**
- Proposed a **computationally economical SymNMF algorithm with convergence guarantees**
- **Promising performance** in real-data experiments

Thank You!!
